## Application Elements (Continued)

3. ☒ Drawing(s) (when necessary as prescribed by 35 USC 113)
- a. ☒ Formal                      Number of Sheets                      17
- b. ☐ Informal                      Number of Sheets                      \_\_\_\_\_
4. ☒ Oath or Declaration
- a. ☐ Newly executed (original or copy)                      ☐ Unexecuted
- b. ☒ Copy from a prior application (37 CFR 1.63(d)) (for continuation/divisional application only)
- c. ☒ With Power of Attorney                      ☐ Without Power of Attorney
- d. ☐ DELETION OF INVENTOR(S)  
Signed statement attached deleting inventor(s) named in the prior application,  
see 37 C.F.R. 1.63(d)(2) and 1.33(b).
5. ☐ Incorporation By Reference (usable if Box 4b is checked)  
The entire disclosure of the prior application, from which a copy of the oath or declaration is supplied under  
Box 4b, is considered as being part of the disclosure of the accompanying application and is hereby  
incorporated by reference therein.
6. ☐ Computer Program in Microfiche (Appendix)
7. ☐ Nucleotide and/or Amino Acid Sequence Submission (if applicable, all must be included)
- a. ☐ Paper Copy
- b. ☐ Computer Readable Copy (identical to computer copy)
- c. ☐ Statement Verifying Identical Paper and Computer Readable Copy

## Accompanying Application Parts

8. ☐ Assignment Papers (cover sheet & document(s))
9. ☐ 37 CFR 3.73(B) Statement (when there is an assignee)
10. ☐ English Translation Document (if applicable)
11. ☒ Information Disclosure Statement/PTO-1449                      ☒ Copies of IDS Citations
12. ☒ Preliminary Amendment
13. ☒ Acknowledgment postcard
14. ☒ Certificate of Mailing
- ☐ First Class                      ☒ Express Mail (Specify Label No.): EL080833155US

**PRELIMINARY AMENDMENT**

Sir:

Before examination of the above-identified application, and before calculation of any fees, please amend the above-identified application as follows:

At page 1, before the first full paragraph, please insert:

--CROSS REFERENCE TO RELATED APPLICATIONS

This application is a divisional of U.S. Patent Application Serial No. 08/919,339 entitled "METHOD AND DEVICE FOR GENERATING A SINGLE-USE FINANCIAL ACCOUNT NUMBER" filed in the name of Jay S. WALKER; Bruce SCHNEIER; Sanjay K. JINDAL; and Daniel E. TEDESCO on August 28, 1997. --

IN THE CLAIMS

Kindly cancel claims 1-14, 17, 20-22, 24, and 26-27 without prejudice.

REMARKS

The Examiner has issued a restriction requirement in the patent application, in response to which applicants have elected group I for prosecution. The applicants have filed this amendment to pursue claims, 16, 19, 23, 25, 28 and 29, representing the Examiner's group II.

If there are any issues that remain, or if the Examiner has suggestions for expediting allowance of the present application, the Examiner is kindly invited to contact Kurt Maschoff at telephone number (203) 705-7020 or via electronic mail at Kurt.Maschoff@WalkerDigital.com.

Please charge any additional fees that may be required for this Amendment, or credit any overpayment to Deposit Account No. 50-0271. A copy of this authorization is included for such purpose.

16. An apparatus for verifying a second account identifier for use in place of a first account identifier, comprising:  
a processing unit, said processing unit including a cryptographic processor;  
a communications unit, connected to said processing unit, operable to transmit and receive information regarding a second account identifier for use in place of a first account identifier; and  
a memory device connected to said processing unit, said memory device containing  
a private cryptographic key,  
a first data element,  
a second data element and  
a program, adapted to be executed by said processing unit, to  
receive the second account identifier,  
extract from the second account identifier a third data element and a  
fourth data element,  
decrypt the third data element using the private cryptographic key  
and the fourth data element,  
compare the decrypted third data element with the first data element  
in a first comparison,  
compare the fourth data element with the second data element in a  
second comparison, and  
verify the second financial account identifier in accordance with the  
first comparison and the second comparison.

19. A method for verifying a second account identifier for use in place of a first account identifier, comprising the steps of:  
providing a memory device containing a private cryptographic key, a first data element and a second data element;  
receiving a second account identifier;  
extracting from the second account identifier a third data element and a  
fourth data element;  
decrypting the third data element using the private cryptographic key and  
the fourth data element;  
comparing the decrypted third data element with the first data element in a  
first comparison;  
comparing the fourth data element with the second data element in a second  
comparison; and  
verifying the second account identifier in accordance with the first  
comparison and the second comparison.

23. An apparatus for verifying a second account identifier for use in place of a first account identifier, comprising:  
a processing unit;  
a communications unit, connected to said processing unit, operable to transmit and receive information regarding a second account identifier; and  
a memory device connected to said processing unit, said memory device containing  
data representing a plurality of predetermined account identifiers,

data representing a status for each of said plurality of predetermined account identifiers, and

a program, adapted to be executed by said processing unit, to

receive said second account identifier,

compare said second account identifier with at least one of said plurality of predetermined account identifiers to identify one predetermined account identifier matching said second account identifier, and

verify said second account identifier in accordance with said comparing step and the data representing the status of said one predetermined account identifier.

25. A method for verifying a second account identifier for use in place of a first account identifier, comprising the steps of:

providing a memory device containing

data representing a plurality of predetermined account identifiers and

data representing a status for each of said plurality of predetermined account identifiers;

receiving a second account identifier;

comparing said second account identifier with at least one of said plurality of predetermined account identifiers to identify one predetermined account identifier matching said second account identifier; and

verifying said second account identifier in accordance with said comparing step and the data representing the status of said one predetermined account identifier.

28. A method for verifying a second account identifier for use in place of a first account identifier, comprising the steps of:

receiving a plurality of second account identifiers, each second account identifier being different from remaining second account identifiers; and

verifying that each of the plurality of second account identifiers indicates a first account identifier.

29. The method of claim 28, in which the first account identifier and each second account identifier respectively comprise sixteen digits.

METHOD AND DEVICE FOR GENERATING A SINGLE-USE  
FINANCIAL ACCOUNT NUMBER

BACKGROUND OF THE INVENTION

This invention relates to a method and a device for generating a single-use, transaction-specific financial account number, thereby providing a high level of security for financial transactions, particularly credit card transactions.

There are over 500 million general purpose, retail, oil and other credit card accounts in the United States (hereafter called "cards"). Worldwide the figure is almost 1 billion such cards. Typically, each authorized user of an account is issued a credit card: a physical plastic object with an embossed account number and cardholder name appearing on its face. Anti-counterfeiting indicia, such as holograms, photographs or signatures, may also appear on the card to discourage wrongful usage.

Since the credit card number is unchanging, there is a risk of fraudulent use by anyone who steals the number. The key element of defense against a fraudulent user impersonating the authentic cardholder is signature verification. A signature area appears on the back of most cards, and when a person receives a new credit card, he is instructed to sign his name on the back of the card. A merchant who accepts the card will then be able to compare the signature specimen that

00542676-040300

appears on the back of the card to the signature on the sales draft signed by the consumer at the time of purchase. In some cases, the merchant may also ask for photo ID before accepting the card or as a method of checking that the signatures are for the person whose name appears on the face of the card.

In addition to examining the signature on the card, most merchants who accept credit cards use a small device known as an authorization terminal. The authorization terminal is capable of reading information disposed on a magnetic stripe located on the back of the credit card. In some cases, this stripe also contains other difficult-to-counterfeit information. To process a credit card purchase, the merchant passes the card through the magnetic stripe reader of the terminal and enters the amount of the purchase. The information is then sent by the device over a phone or wireless connection to a central database for account number verification and purchase authorization. A card that has been reported lost or stolen is declined. If magnetic stripes on credit cards become damaged and unreadable, the authorization terminal permits manual entry of the credit card number as it appears embossed on the face of the card.

With the dramatic growth of direct marketing, an increasing share of all card purchases are being made without the physical presentation of the card to the selling merchant. Instead, the consumer simply relays the card number to the merchant, and the merchant enters the card number into a computer terminal which is also designed to handle the order processing function. As electronic commerce grows over the next decade, the percentage of such remote, non-face-to-face purchases can be expected to grow. This poses an increasingly acute problem for the entire credit card system,

09542676-040300

since credit card numbers are highly insecure.

To protect against thieves fraudulently creating credit card numbers and then using them for remote purchasing, a check-digit algorithm is typically employed for credit card account numbers which makes it comparatively difficult (approximately 1 chance in 500,000) to pick a random 16-digit number that is also a valid credit card account number. In addition, since not every valid credit card account number is currently in use, simply making up a valid number is, in itself, not enough to get an authorization code from the central authorizing network. In addition to passing the check-digit test, a bank must have issued that number to an active customer.

To further help combat mail-order based credit card fraud, both Visa and MasterCard have deployed databases that allow a merchant to verify that a given credit card account number is connected to a specific billing address. Visa calls this service the Address Verification Service. The theory behind the service is that a thief (for example, a dishonest restaurant waiter) might be able to use a credit card receipt slip to steal an active account number, but if he tries to use that number for a mail order purchase he would not know the correct address associated with that number. Even if a thief were to obtain the cardholder's address, this service can allow a merchant to compare the shipping address of the catalog order to the current billing address for that account number and thus possibly identify any suspicious activity.

Currently, credit cards also incorporate an expiration date after which they are no longer valid. These dates are typically one to two years after the card is issued. The reason for an expiration date is to reduce the issuing bank's

00542676-040300

In addition, credit card information and transaction information may be encrypted using well known encryption schemes like RSA's public key cryptography. For example, SET is a joint Visa/MasterCard standard for encrypting credit card numbers transmitted over the Internet.

a) Theft of cards: Any conventional credit card which is stolen can be misused, either at a merchant's establishment by forging the signature on the card onto a sales slip, or by ordering merchandise or services remotely.

A large-scale attack on credit-card number security would threaten the entire credit card system. For example, if someone were to steal 1 million active credit card account

With the advent of almost instantaneous worldwide money transfers, a band of organized thieves could clear hundreds of millions or even billions of dollars of charges through the authorization system and then wire that money to a safe haven before cardholders suspected that their cards had been charged an unauthorized amount. If the theft also involved data revealing each account's unused available credit line, such criminal activity might be even harder to detect before it was too late to rescind the wire transfers of stolen money.

Smart cards are used to authenticate card users and to authenticate the card/user combination to a third party. These cards are also used for controlling access to computer systems and databases and entry into secure areas. Northern Telecom offers a credit card sized smart card called Entrust which contains a microchip that stores encoded, private keys.

Token Code," describes a method for enhancing security for a private key stored in a smart card. A user input PIN is combined algorithmically with a code resident in the smart card to produce the private key. The private key is not stored in the smart card except for short intervals when the card is actually being used by an authorized user who has input his PIN.

#### SUMMARY OF THE INVENTION

This invention provides a method and a device to facilitate secure electronic commerce, secure remote credit card purchases, and secure conventional credit card purchases wherein the customer is assured that the merchant or an intercepting third party cannot misuse any credit card information.

According to one aspect of our invention, a method for generating a single-use financial account identifier is provided which includes the steps of accessing a first data element specific to an account; accessing a second data element including transaction-specific data; and combining the first data element and the second data element to produce the single-use financial account identifier.

According to another aspect of our invention, a device for facilitating credit transactions is provided which includes a processing unit including a cryptographic processor. The device also includes an input unit connected to the processing unit for inputting information thereto, and a display unit connected to the processing unit for displaying a processing result. In addition, the device includes a memory device connected to the processing unit. The memory

09542676 040300

device contains a private cryptographic key, a first data element, a second data element and a program adapted to be executed by the processing unit. In accordance with the program, the processing unit encrypts the first data element using the private cryptographic key and the second data element, modifies the second data element, combines the encrypted first data element and the second data element to generate a single-use financial account identifier, and displays the single-use financial account identifier using the display unit.

According to a further aspect of our invention, a system for verifying a financial account identifier is provided which includes a processing unit including a cryptographic processor. The system also includes a communications unit, connected to said processing unit, for transmitting and receiving information regarding the financial account identifier, and a memory device. The memory device contains a private cryptographic key, a first data element, a second data element and a program adapted to be executed by the processing unit. In accordance with the program, the processing unit receives a single-use financial account identifier, extracts therefrom a third data element and a fourth data element, decrypts the third data element using the private cryptographic key and the fourth data element, compares the decrypted third data element with the first data element in a first comparison, compares the fourth data element with the second data element in a second comparison, and verifies the received financial account identifier in accordance with the first comparison and the second comparison.

According to still another aspect of our invention, a method for providing a single-use financial account identifier

005412676 040300

includes the steps of: providing a memory storing data representing a plurality of predetermined single-use financial account identifiers, data representing a status for each single-use financial account identifier, and data representing a pointer to one of the single-use financial account identifiers; identifying the single-use financial account identifier based on the pointer data; and transmitting a signal to an output device to present the single-use financial account identifier.

According to a further aspect of our invention, a device for providing a single-use financial account identifier is provided which includes a memory, an output device and a processor coupled to the memory and to the output device. The memory stores data representing a plurality of predetermined single-use financial account identifiers, data representing a status for each of the predetermined single-use financial account identifiers, and data representing a pointer to one of the predetermined single-use financial account identifiers. The output device presents the single-use financial account identifier. The processor is configured to identify the single-use financial account identifier based on the data representing a pointer, and to transmit a signal to the output device to present the single-use financial account identifier.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Figure 1 is a schematic diagram of a device 100 for generating a single-use credit card number in accordance with this invention. This device is preferably a smart card, hereinafter referred to as the "device." The device has a keypad 103, a display screen 102, a memory 104 and a central processor 101. Memory 104 contains a key 601, and CPU 101 contains a cryptographic processor. The device may be activated through the input of a unique cardholder identifier such as a personal identification number (PIN) through the keypad 103. Alternatively, the device may include a biometric interface 105, and be activated by the input of a suitable biometric record such as the cardholder's fingerprint.

Figure 2 is a schematic diagram showing further details of the central processor 101 of device 100. The central

Figure 3A is a schematic diagram of the environment in which the method and system of the present invention are used. A cardholder 301, wishing to purchase goods or services from a merchant 302 (not necessarily in person), transmits a single-use credit card number 300 to the merchant. The merchant 302 transmits the single-use credit card number 300 to a credit card issuer 303. The credit card issuer 303 returns an authorization 310 to the merchant, based on which the merchant delivers the desired goods or services 320 to the cardholder.

This number could be only a few digits long since it does not have to be unique to each merchant.

The device then generates a single-use credit card number (step 360); details of the card number generation are explained below. The number is unique for the specific input variables set by the cardholder or by the device. It may also be unique to the specific date and time to avoid so-called "replay" attacks for that card at that merchant with that exact purchase amount. The single-use credit card number is preferably a 16-digit number that can be recognized as a conventional credit card number.

The cardholder transmits the single-use number to the merchant (step 361), and the merchant enters the single-use number into an authorization terminal connected to a central credit card processing system maintained by the credit card issuer (step 362). A check digit may be included in the number to prevent the incorrect keying of the number. The number is sent to the credit card processing system for authorization (step 363). The central system processor maps the single-use credit card number onto a conventional credit card account and determines whether the transaction is authorized (step 380); if so, the central system returns an authorization code for display on the merchant's authorization terminal (step 390); if not, the central system transmits an authorization failed message for display on the merchant's authorization terminal (step 395).

Throughout this discussion, the term "credit card number" refers to a number that is used only one time to perform a specific transaction, and is generated using the device 100; in contrast, the term "account number" refers to an unchanging identifier for the cardholder which is stored in a database maintained by the card issuer.

00543676.040300

#### First Embodiment (Device Private Key Encryption)

In this embodiment, the single-use credit card number is generated by the device cryptoprocessor 205, using a private key 601 stored in the device memory 104 (preferably the ROM 204). The encryption data changes with each use of the card, so that the single-use encrypted credit card number is different for each transaction. This credit card number is distinct from the unchanging account number identifying the particular cardholder. It should be noted that knowledge of the account number does not allow an attacker to generate a valid single-use credit card number.

When the single-use credit card number is transmitted to a merchant, the merchant passes the number to the card issuer's central processor for authorization. The central processor decrypts the number based on a known algorithm, determines the true account number, and either authorizes or denies the charge.

Figure 4 is a schematic diagram of the credit card issuer's central processor 400. The processor includes a central processing unit (CPU) 401. The CPU is connected to a clock 402, a random-access memory (RAM) 403, a read-only memory (ROM) 404, a cryptographic processor 405, and a communication port 406 for communication with the merchant's central processor. In addition, the CPU 401 is connected to a storage device 410, which includes a credit card account holder database 411, a credit card account private key database 412, and a credit card transaction database 413.

The data structure of the credit card account holder database 411 is shown in Figure 5. Each record in the database

00543675-040300

includes the cardholder account number 501, the cardholder's name 502, address 503 and telephone number 504, the original credit line 505 associated with the account, the amount of credit currently available (available credit line 506), and the expiration date 507.

Figure 6 shows the fields of the credit card account private key database 412. Each entry of this database has the cardholder private key 601 and the associated cardholder account number 501. The private key is thus stored in both the device memory 104 and the database 412. An additional secret piece of information, called a "nonce" 602, is associated with the account number. The nonce is also stored in the device memory 104. The nonce need not be as long as the account number, but should not be easily derived therefrom.

Figure 7 shows the fields of the credit card transaction database 413. Each record of this database corresponds to one transaction using the card, and includes the account number 501, the expiration date 507 of the card, the transaction amount 702, the merchant identification number 703 and an initialization variable 704. The initialization variable 704 is used to ensure that each credit card number is unique to the particular transaction, thereby preventing a "replay" attack.

In this embodiment, the device memory 104 has stored therein the private key 601, the nonce 602, the initialization variable 704 and the account number 501. The initialization variable is set at 0 (zero) when the card is newly issued, and is incremented each time a single-use credit card number is generated.

A credit card number consists of an m-bit initialization variable (abbreviated IV), an a-bit account number, and an n-bit nonce (abbreviated N), where  $m+a+n = 53$ . It should be noted that the nonce may take the place of the check code employed with conventional credit card numbers. If  $n = 16$ , then the probability that an attacker can generate a valid credit card number is 1 in  $2^n = 65536$ . The parameter n can be varied to change the probability as desired.

The steps for generating an encrypted single-use credit card number according to this embodiment are shown in Figure 8. In step 801, the device central processor 101 retrieves the nonce 602 and the initialization variable 704 from the device memory 104. In step 802, the nonce is encrypted using the user's private key K and the IV. Thus

$$C = E_k(N, IV)$$

where C represents the encrypted nonce. Both N and C are n-bit values.

The central processor 101 then retrieves the account number from the device memory 104 (step 803). In step 804, the encrypted nonce C, the initialization variable IV, and account number A are concatenated to form an encrypted, single-use credit card number CCN:

CCN = C\_IV\_A, where \_ denotes concatenation.

The initialization variable is incremented and the result is stored in the device memory 104 (step 805):

$$IV = IV + 1$$

The resulting credit card number CCN is then displayed on the display screen 102 (step 806) and read, shown or otherwise transmitted to the merchant. The merchant transmits this number to the issuer's central processor 400 for authorization of the transaction.

Figures 9A and 9B show the steps for generating an authorization code for the transaction. In step 901 the issuer's central processor 400 receives the single-use credit card number transmitted by the merchant.

To verify the card number, the credit card issuer's central processor first extracts the encrypted nonce C, the initialization variable IV, and account number A from the credit card number (step 902). The processor then retrieves the extracted account number from the cardholder account database 411 (step 903), and determines whether the account number is valid (step 904). If the account number is not valid, the transaction is aborted (step 905). If the account number is valid, the processor looks up the account number in

In step 921, the processor retrieves the card holder's private key K in the private key database 412. The private key K then is used to decrypt the encrypted nonce (step 922). This recovers the original nonce N:

The decrypted nonce N is compared against the nonce 602 stored in the account private key database 412 (step 923). If they match (step 924) then the credit card number is considered valid; otherwise the transaction is aborted (step 925).

Approval criteria are issuer specific and may include, but are not limited to, the following: account must be in good standing (not past due); sufficient credit must be available (some issuers may approve purchases that exceed available credit by a specified margin), the card should not have been reported stolen/lost; and the account should not be closed.

There are two types of ciphers which can be used to encrypt

Accordingly, one possible encryption method uses a stream cipher. Conventional ciphers use a secret key  $k$  to produce a stream of data. The data is then combined with the unencrypted data (e.g. by XORing them together) to produce the encrypted text. On the other hand, to encrypt an  $n$ -bit value  $N$  using initialization variable  $IV$  and key  $k$ , a stream cipher may be used to generate  $n(IV + 1)$  bits of data, with  $N$  then combined with the last  $n$  bits of the resulting data.

1. The input of the block cipher  $I_1$  consists of the IV concatenated with a 1 - m bit shift register (where m is the number of bits in the IV and we are using a 1-bit block cipher). Let  $S_i$  be the state of the shift register.

$$S_0 = 1$$

and

In fact,  
for all  $i$ .

$$I_1 = IV_{-S_1}$$

In fact,  
for all  $i$ .

$$C_i = f(I_i, k)_0 \oplus P_i$$

where  $f$  is the encryption function of the block cipher and  $f(I/k)_0$  denotes bit 0 of the encryption of  $I$  with key  $k$ .

$$S_{i+1} = (S_i < 1) \_ C_i$$

where  $S \ll 1$  denotes shifting  $S$  left 1 bit.

To decrypt the data a nearly identical algorithm is used except that  $P_i$  and  $C_i$  are reversed. So the second step of the algorithm is all that changes and it becomes:

$$P_i = f(I_i, k)_0 \oplus C_i$$

where  $f$  is the encryption function of the block cipher and  $f(I, k)_0$  denotes bit 0 of the encryption of  $I$  with key  $k$ .

Suitable block ciphers include Triple-DES, IDEA and Blowfish. Suitable stream ciphers include RC4, SEAL and A5. All of these algorithms are discussed in B. Schneier, "Applied Cryptography," John Wiley & Sons, 2d ed. 1996.

The primary defense against replay attacks in this embodiment is checking that the same initialization variable IV is not used twice for any particular account number. When the credit card is issued the internal IV is preferably set to 0. Each time the credit card is used the IV increments by 1. Therefore, as long as the cardholder does not use the credit card more than  $2^m$  times (where the IV is m bits long) the

same initialization variable will never be repeated. Preferably, the credit card issuer keeps track of the IVs that the card holder has used. This can be done with a simple bit array where entry  $a$  of the array indicates that IV  $a$  has been used if and only if it is set to 1.

As stated earlier,  $m = 9$  is probably sufficient for most cardholders. This means that the card issuer needs only keep track of a 512-bit array for each such credit card. This is very inexpensive. In addition, if the issuer notices that the cardholder has nearly exhausted his IVs, then it can issue the cardholder a new card.

Another attack against this system would be to flood the central server with bogus credit card numbers (otherwise known as a denial-of-service attack). One way to make this attack more difficult is to spread the authorization processing load across several servers which all have the capability of verifying a credit card number. If they receive a valid credit card number, they can coordinate with the central server to perform the credit card transaction.

Ideally, the load should be spread evenly across several different servers. A simple way to do this is to set up  $p$  servers and assign each a unique number in the range 0 to  $2^p - 1$ . Next, for every credit card number that must be verified, check a prespecified set of  $p$  bits of the credit card number and assign the verification to the server with the corresponding number. For example, if the  $p$  specified bits of the credit card number give "14," assign the verification to the server numbered "14."

For the primary embodiment, there are  $2^{53}$  possible credit card numbers. A central authority might be established to assign

09542676 "040300

ranges of account numbers to individual credit card companies. Once a company receives an  $r$ -bit range of account numbers it may further split the range of numbers up as desired. Ultimately the issuer should decide upon the size of the nonce ( $n$  bits), the account number ( $a$  bits), and the size of the IV ( $m$  bits) so that  $n+a+m = r$ . Note that the account number should include those bits assigned by the central authority. Also, different card holders can have different values of  $n$ ,  $a$ , and  $m$  even if they receive their cards from the same credit card company.

After a cardholder's card expires, his account number can be reused. The next credit card issued with that account number would use a different nonce and private key. This will ensure that any credit card numbers generated with the old credit card will not match any new credit card numbers with better than random chance.

In an alternative to the present embodiment, timestamps could be included with the nonce during encryption. Then, credit cards could be used in conjunction with a clock. When creating the credit card the credit card issuer should start the clock at 0 and note the offset from its own clock, storing the difference with the card holder's account information (for example in the database 411). Then when a credit card issuer desires to validate a timestamp created by the credit card, it may simply add the timestamp to the offset stored with the card holder's account and then compare the result against its own clock. If the time falls within a specified time window then the timestamp should be considered valid.

In order for the credit card issuer to verify a single-use credit card number, it must know to which account the credit

card number belongs. Instead of encoding the account number as part of the credit card number, the name that appears on the card could take the place of the account number. In that case every credit card must have a different name printed on the card. The trade-off in this instance is that many more bits become available in the credit card number since they are not used to encode the account number. They can then be used to encode a timestamp, purchase information, or even merchant information.

#### Second Embodiment (Lists of Single-Use Credit Card Numbers)

In this embodiment, the device memory 104 includes a database with a list of single-use credit card numbers and a flag for each number indicating whether the number has already been used. The single-use credit card numbers are assigned to the cardholder by the credit card issuer.

One method to assign single-use credit card numbers is as follows. There are  $2^{53}$  possible credit card numbers. Some sort of central authority could assign ranges of account numbers to individual credit card companies. Once a company receives an  $r$ -bit range of account numbers they can further split the range of numbers up however they please. Ultimately, the credit card company would decide upon the size of the nonce ( $N$  bits), the account number ( $A$  bits), and the size of the IV ( $m$  bits) so that  $n+a+m = r$ . The account number would include those bits assigned by the central authority. Also, different card holders can have different values of  $n$ ,  $a$ , and  $m$  even if they received their cards from the same credit card company. It is simply up to the company to keep track of the appropriate information.

09542676.040300

After a card holder's card expires their account number can be reused. The next credit card issued with that account number should use a different nonce and private key. This will ensure that any credit card numbers generated with the old credit card will not match any new credit card numbers with better than random chance.

The steps for obtaining a single-use credit card number according to this embodiment are shown in Figure 10. In step 1001, the cardholder enters his unique identifier (for example, a PIN or biometric data) into the device. The device determines whether the identifier is valid for the device (step 1002); if not, access to the device is denied (step 1004). If the identifier is valid, the device searches the single-use credit card number database in the device memory 104 for a single-use credit card number (step 1003). If a single-use credit card number is available (step 1005), it is displayed on the device display screen 102 (step 1007); if not, a message is displayed instructing the cardholder to obtain a new device (with a new list of single-use credit card numbers) from the credit card issuer (step 1006). The database in the device memory 104 is then updated to change the status of the number from "not used" to "used" (step 1008).

A schematic diagram of the credit card issuer's central processor according to this embodiment is shown in Figure 12. The processor 1200 includes a central processing unit (CPU) 1201. The CPU is connected to a clock 1202, a random-access memory (RAM) 1203, a read-only memory (ROM) 1204, and a communication port 1206 for communication with the merchant's central processor, similar to the first embodiment. In addition, the CPU 1201 is connected to a data storage device 1210, which includes a credit card account holder database

09542676.040300

The fields of the credit card number database 1212 are shown in Figure 13. Each cardholder account number 501 is associated with the cardholder name 502 and a list of credit card numbers 1301; each credit card number has associated therewith its status 1302 (used or not used).

The steps for generating an authorization code for a credit transaction in this embodiment are shown in Figures 11A and 11B. In step 1101, the cardholder provides the merchant with a single-use credit card number displayed on the device (see step 1007 of Figure 10). The merchant then transmits the single-use credit card number and the transaction amount to the credit card issuer's central processor 1200 (step 1102). The central processor searches the credit card number database 1212 to identify the account holder of the transmitted single-use credit card number (step 1103), and determines whether the transmitted credit card number matches a credit card number listed in the credit card number database (step 1104). If there is no match, the credit card number is considered invalid, and the transaction is aborted (step 1105). If there is a match, the credit card number is considered valid, and the central processor checks the status 1302 of the credit card number to determine whether the

credit card number has already been used (step 1106). If so, the number is no longer valid, and the transaction is aborted (step 1107).

If the cardholder's account meets the credit card issuer's approval criteria (step 1121), then the issuer's central processor generates an authorization code and transmits the code to the merchant (step 1123). If not, the transaction is aborted (step 1122). Finally, in step 1124, the issuer's central processor changes the status 1302 of the credit card number from "not used" to "used."

While the present invention has been described above in terms of specific embodiments, it is to be understood that the invention is not limited to the disclosed embodiments. On the contrary, the present invention is intended to cover various modifications and equivalent structures included within the spirit and scope of the appended claims.

0054675-040300

We claim:

1. A method for generating a single-use financial account identifier, comprising the steps of:
  - accessing a first data element, specific to an account;
  - accessing a second data element including transaction-specific data; and
  - combining said first data element and said second data element to produce said single-use financial account identifier.
2. The method of claim 1 wherein the step of accessing said first data element includes accessing an account identifier.
3. The method of claim 2 wherein said account identifier is alpha-numeric.
4. The method of claim 1 wherein the step of accessing said second data element includes accessing a time.
5. The method of claim 1 wherein the step of accessing said second data element includes accessing a payment amount.
6. The method of claim 1 wherein said step of accessing said second data element includes accessing a merchant identifier.
7. The method of claim 1 wherein the step of accessing said first data element includes encrypting said first data element.
8. The method of claim 7 wherein the encrypting step is based on a private key encryption technique.
9. The method of claim 1 wherein the combining step is based on a hashing function.

09543676-040300

10. The method of claim 1 wherein the combining step includes encrypting said first data element and said second data element.

11. The method of claim 10 wherein the encrypting step is based on a private key encryption technique.

12. The method of claim 1, further comprising the step of accessing a third data element including a static account identifier, and wherein said combining step includes combining said third data element with said first data element and said second data element.

13. The method of claim 1, further comprising the step of updating said second data element to initialize for a future transaction.

00542676 040300

14. A device for facilitating a financial account transaction, comprising:

a processing unit, said processing unit including a cryptographic processor;

an input unit connected to said processing unit for inputting information thereto;

a display unit connected to said processing unit for displaying a processing result therefrom; and

a memory device connected to said processing unit, said memory device containing a private cryptographic key, a first data element, a second data element and a program, adapted to be executed by said processing unit, to encrypt the first data element using the private cryptographic key and the second data element, modify the second data element, combine the encrypted first data element and the second data element to generate a single-use financial account identifier, and display the single-use financial account identifier using said display unit.

15. An apparatus for facilitating a financial account transaction, comprising:

a processing unit;

an input device connected to said processing unit for inputting a financial account identifier thereto;

a transmitting/receiving device connected to said processing unit for transmitting the financial account identifier for verification thereof and for receiving information regarding authorization of the transaction; and

an output device connected to said processing unit for outputting the information regarding authorization of the transaction,

wherein the financial account identifier is a single-use financial account identifier containing information specific to the transaction.

00542676-040300

16. An apparatus for verifying a financial account identifier, comprising:

a processing unit, said processing unit including a cryptographic processor;

a communications unit, connected to said processing unit, for transmitting and receiving information regarding the financial account identifier; and

a memory device connected to said processing unit, said memory device containing a private cryptographic key, a first data element, a second data element and a program, adapted to be executed by said processing unit, to receive a single-use financial account identifier, extract therefrom a third data element and a fourth data element, decrypt the third data element using the private cryptographic key and the fourth data element, compare the decrypted third data element with the first data element in a first comparison, compare the fourth data element with the second data element in a second comparison, and verify the received financial account identifier in accordance with the first comparison and the second comparison.

09542676 040300

providing a memory device containing a private cryptographic key, a first data element, and a second data element;

```
modifying the second data element;
```

displaying the single-use financial account  
r.

providing a processing unit;

transmitting the financial account identifier for  
ion thereof;

outputting the information regarding authorization  
ansaction,

wherein the financial account identifier is a single-use financial account identifier containing information specific to the transaction.

19. A method for verifying a single-use financial account identifier, comprising the steps of:

providing a memory device containing a private cryptographic key, a first data element and a second data element;

receiving said single-use financial account identifier;

extracting from said single-use financial account identifier a third data element and a fourth data element;

decrypting the third data element using the private cryptographic key and the fourth data element;

comparing the decrypted third data element with the first data element in a first comparison;

comparing the fourth data element with the second data element in a second comparison; and

verifying said single-use financial account identifier in accordance with the first comparison and the second comparison.

09544676-040300

20. A device for providing a single-use financial account identifier, said device comprising:

a memory storing data representing a plurality of predetermined single-use financial account identifiers, data representing a status for each of said plurality of predetermined single-use financial account identifiers, and data representing a pointer to one of said plurality of predetermined single-use financial account identifiers;

an output device for presenting said single-use financial account identifier; and

a processor coupled to said memory and to said output device, said processor being configured to identify said single-use financial account identifier based on said data representing a pointer, said processor being further configured to transmit a signal to said output device to present said single-use financial account identifier.

21. A device according to claim 20, further comprising an input device adapted to transmit an input signal representing a request to present said single-use financial account identifier, wherein said processor is coupled to said input device and said processor is further configured to receive said input signal from said input device.

22. A device according to claim 20, wherein said processor is further configured to update said data representing a pointer and to update said data representing a status.

09543636.040300

23. An apparatus for verifying a single-use financial account identifier, comprising:

a processing unit;

a communications unit, connected to said processing unit, for transmitting and receiving information regarding said single-use financial account identifier; and

a memory device connected to said processing unit, said memory device containing data representing a plurality of predetermined single-use financial account identifiers, data representing a status for each of said plurality of predetermined single-use financial account identifiers, and a program, adapted to be executed by said processing unit, to receive said single-use financial account identifier, compare said single-use financial account identifier with each of said plurality of predetermined single-use financial account identifiers to identify one predetermined single-use financial account identifier matching said single-use financial account identifier, and verify said single-use financial account identifier in accordance with said comparison and the data representing the status of said one predetermined single-use financial account identifier.

095443676 "040300

providing a memory storing data representing a plurality of predetermined single-use financial account identifiers, data representing a status for each of said plurality of predetermined single-use financial account identifiers, and data representing a pointer to one of said plurality of predetermined single-use financial account identifiers;

25. A method for verifying a single-use financial account identifier, comprising the steps of:

```

        receiving said single-use financial account
        identifier;

```

verifying said single-use financial account identifier in accordance with said comparison and the data representing the status of said one predetermined single-use financial account identifier.

ABSTRACT OF THE DISCLOSURE

09542676-040300

A device for facilitating financial account transactions is described which includes a processing unit including a cryptographic processor. The device also includes an input unit, a display unit and a memory device 5 connected to the processing unit. The memory device contains a private cryptographic key, a first data element and a second data element. The processing unit encrypts the first data element using the private cryptographic key and the second data element, modifies the second data element, 10 combines the encrypted first data element and the second data element to generate a single-use financial account identifier, and displays the single-use financial account identifier. This identifier is then transmitted to a central processor for authorization of the transaction. The central 15 processor extracts and decrypts data elements from the transmitted identifier using the private cryptographic key, compares those data elements with data elements stored in a memory, and verifies the single-use financial account identifier in accordance with the comparison.

COMBINED DECLARATION AND POWER OF ATTORNEY  
FOR PATENT APPLICATION

(Page 1)

**COPY**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled METHOD AND DEVICE FOR GENERATING A SINGLE-USE FINANCIAL ACCOUNT NUMBER, the specification of which ☒ is attached hereto ☐ was filed on \_\_\_\_\_ as United States Application No. or PCT International Application No. \_\_\_\_\_ and was amended on \_\_\_\_\_ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR §1.56.

I hereby appoint the following attorneys to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith: Joseph M. Fitzpatrick (Registration No. 17,398), Lawrence F. Scinto (Registration No. 18,973), William J. Brunet (Registration No. 20,452), Robert L. Baechtold (Registration No. 20,860), John A. O'Brien (Registration No. 24,367), John A. Krause (Registration No. 24,613), Henry J. Renk (Registration No. 25,499), Peter Saxon (Registration No. 24,947), Anthony M. Zupcic (Registration No. 27,276), Charles P. Baker (Registration No. 26,702), Stevan J. Bosses (Registration No. 22,291), Edward E. Vassallo (Registration No. 29,117), Ronald A. Clayton (Registration No. 26,718), Lawrence A. Stahl (Registration No. 30,110), Laura A. Bauer (Registration No. 29,767), Leonard P. Diana (Registration No. 29,296), David M. Quinlan (Registration No. 26,641), Nicholas N. Kallas (Registration No. 31,530), William M. Wannisky (Registration No. 28,373), Lawrence S. Perry (Registration No. 31,865), Robert H. Fischer (Registration No. 30,051), Christopher Philip Wrist (Registration No. 32,078), Gary M. Jacobs (Registration No. 28,861), Michael K. O'Neill (Registration No. 32,622), Bruce C. Haas (Registration No. 32,734), Scott K. Reed (Registration No. 32,433), Scott D. Malpede (Registration No. 32,533), Fredrick M. Zullo (Registration No. 32,452), Richard P. Bauer (Registration No. 31,588), Warren E. Olsen (Registration No. 27,290), Abigail F. Cousins (Registration No. 29,292), Steven E. Warner (Registration No. 33,326), Thomas J. O'Connell (Registration No. 33,202), Penina Wollman (Registration No. 30,816), David L. Schaeffer (Registration No. 32,716), Jack S. Cubert (Registration No. 24,245), Mark A. Williamson (Registration No. 33,628), Jean K. Dudek (Registration No. 30,938), Raymond R. Mandra (Registration No. 34,382), Dominick A. Conde (Registration No. 33,856), Pasquale A. Razzano (Reg. No. 25,512), John W. Behringer (Registration No. 23,086), Robert C. Kline (Registration No. 17,739), Mark J. Itri (Registration No. 36,171), Michael P. Sandomato (Registration No. 35,345), Jack M. Arnold (Registration No. 25,823), John D. Carlin (Registration No. 37,292), Daniel S. Glueck (Registration No. 37,838), Joseph W. Ragusa (Registration No. 38,586), Brian L. Klock (Registration No. 36,570), Anne M. Maher (Registration No. 38,231), William J. Zak, Jr. (Registration No. 38,668), Thomas D. Pease (Registration No. 35,317), Bruce M. Wexler (Registration No. 35,409), Robert S. Mayer (Registration No. 38,544), Errol B. Taylor (Registration No. 39,853), Matthew J. Golden (Registration No. 35,161), Sean W. O'Brien (Registration No. 37,689), Dolores A. Moro-Grossman (Registration No. 33,972), T. Thomas Gellenthien (Registration No. 39,683), Douglas Sharrott (Registration No. 39,832), Gordon F. Sieckmann (Registration No. 28,667), Jay H. Anderson (Registration No. 38,371), Jeffrey L. Brandt (Registration No. 31,490) and Robert R. Lech (Registration No. 37,169).

**REVOCATION AND APPOINTMENT OF POWER OF ATTORNEY**

Sir:

Walker Asset Management Limited Partnership, the sole assignee and owner of the entire right, title and interest in the above-identified patent application, hereby revokes all previous powers of attorney and hereby appoints Dean Alderucci (PTO Reg. No. 40,484), Patrick J. Buckley (PTO Reg. No. 40,928), Steven M. Santisi (PTO Reg. No. 40,157), and Kurt M. Maschoff (PTO Reg. No. 38,235) as attorneys of record, all of Walker Digital Corporation located at One High Ridge Park, Stamford, Connecticut 06905-1326, with full power of substitution and revocation, to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith.

Please address all written correspondence to:

Walker Digital Corporation  
One High Ridge Park  
Stamford, CT 06905-1326  
Phone (203) 905-6500  
Fax (203) 595-8266

**Certificate Under 37 C.F.R. § 3.73(b)**

Walker Asset Management Limited Partnership, a limited partnership organized and existing under the laws of the state of Connecticut, certifies that it is the assignee of the entire right, title and interest in the patent application identified above by virtue of either:

- A. ☒ An Assignment from the inventor(s) of the patent application identified above. The assignment was recorded in the U.S. Patent and Trademark Office on August 28, 1997, at Reel 8696, Frame 0332, or for which a copy thereof is attached.

B. ☐ A chain of title from the inventor(s) of the patent application identified above to the current assignee as shown below:

1. From: \_\_\_\_\_ To: \_\_\_\_\_  
The document was recorded in the Patent and Trademark Office at Reel \_\_\_\_\_,  
Frame \_\_\_\_\_, or for which a copy thereof is attached.
2. From: \_\_\_\_\_ To: \_\_\_\_\_  
The document was recorded in the Patent and Trademark Office at Reel \_\_\_\_\_,  
Frame \_\_\_\_\_, or for which a copy thereof is attached.
3. From: \_\_\_\_\_ To: \_\_\_\_\_  
The document was recorded in the Patent and Trademark Office at Reel \_\_\_\_\_,  
Frame \_\_\_\_\_, or for which a copy thereof is attached.
4. From: \_\_\_\_\_ To: \_\_\_\_\_  
The document was recorded in the Patent and Trademark Office at Reel \_\_\_\_\_,  
Frame \_\_\_\_\_, or for which a copy thereof is attached.

C. ☐ Copies of the assignments or other documents in the chain of title are attached.

The undersigned has reviewed all the documents in the chain of title of the patent application identified above and to the best of undersigned's knowledge and belief, title is in the assignee identified above.

The undersigned (whose title is supplied below) is empowered to act on behalf of the assignee.

I hereby declare that all statements made herein of my own knowledge are true, and that all statements made on information and belief are believed to be true; and further, that these statements are made with the knowledge that willful false statements, and the like so made, are punishable by fine or imprisonment, or both, under Section 1001, Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application identified above or any patent issuing thereon.

Walker Asset Management Limited Partnership

Dated: August 19, 1999
